

Project Design Phase

Solution Architecture

Date	03 October 2026
Team ID	SWTID-2026-4310
Project Name	Implement Client Script & UI Policy (Incident)
Maximum Marks	4 Marks

Solution Architecture:

The proposed architecture uses **ServiceNow Incident** as the central application area. UI Policies control dynamic field behaviour, while Client Scripts handle client-side automation and validation. Together, they guide users during Incident form and list interactions and help maintain consistent Incident data.

Architecture Component	Role in the Project
Incident Table	Central ServiceNow table where Incident records and relevant fields are managed.
UI Policy	Applies condition-based field behaviour on the Incident form, including mandatory-field enforcement and reverse behaviour when conditions are no longer true.
UI Policy Action	Controls the selected Incident field behaviour, including the project requirement related to Urgency.
onChange Client Script	Responds when a field value changes and can update related fields immediately.
onSubmit Client Script	Performs save-time validation so incorrect or incomplete Incident data can be prevented from being submitted.
onCellEdit Client Script	Controls validation for direct Incident list editing and helps prevent inappropriate changes through list edits.
Testing	Verifies mandatory-field enforcement, form save validation, reverse-condition behaviour, list-edit blocking, and form-based updates.

Project flow: User action → Incident form/list → UI Policy and Client Scripts → field behaviour / validation → tested Incident update.

The architecture is intended to bridge the project's Incident-management problem and its ServiceNow technology solution by defining the main components, their behaviour, and the way they interact. This follows the uploaded template's focus on describing software structure, characteristics, behaviour, features, development phases, and solution requirements.
